Theophylline

Electrochemical sensor

ABSTRACT

In this study, a novel theophylline (TP) sensor based on MnO₂ nanosheets/ionic liquid-functionalized graphene (MnO₂ nanosheets/IL-graphene) was fabricated. Cyclic voltammetry (CV) was used to evaluate the electrochemical behavior of the modified electrode. The surface concentration of the electroactive species, Γ , was calculated to be approximately $2.316 \times 10^{-10} \text{ mol cm}^{-2}$ for MnO₂ nanosheets on the modified electrode. The resulting system was suitable for electrochemical sensing because of the combined advantages of MnO₂ nanosheets and IL-graphene. The differential pulse voltammetric (DPV) results indicated a high ability of the MnO₂ nanosheets/IL-graphene/GCE to catalyze the oxidation of TP and, hence, to detect it. DPV determination of TP gave linear responses over the concentration range from 1 to 220 μM , and the detection resolution limit was 0.1 μM . Furthermore, the applicability of the MnO₂ nanosheets/IL-graphene/GCE for analysis in real samples was successfully demonstrated.

1. Introduction

Theophylline (TP) is a compound mainly used to treat emphysema, bronchial asthma, cardiac difficulty breathing and bronchitis [1]. Pharmacological action of TP is related to its serum concentrations [2], and the range in which the chemical is effective and safe. Moreover, when taken orally, its absorption is poor because of various factors in the body and multiple differences between individuals. High levels of TP in the blood can lead to poisoning the patient [3]. Because of this, it is crucial to have a method which can detect TP in a simple, rapid, and efficient way. Currently there are some methods for detecting TP, such as liquid chromatography-mass spectrometry (LC-MS) [4], thin-layer chromatography (TLC) [5], high performance liquid chromatography (HPLC) [6], high performance capillary electrophoresis (HPCE) [7], and electrochemical methods [8,9]. Electrochemical measurements, which are continuous, simple, and efficient, are already widely used for detecting xanthine alkaloids. For instance, Zen and coworkers determined trace amounts of TP in tea and drug formulations using

a Nafion[®]/lead-ruthenium oxide pyrochlore chemically modified electrode [10]. The results of 15 successive repeated measurement-regeneration cycles showed a relative standard deviation of 1.3% for 10 μM TP, indicating that the electrode renewal gives a good reproducible surface.

Graphene is a material with excellent electron conductivity [11] because electrons can move freely in its planes due to the presence of π trajectory. Because of its conductivity and wide potential window, using graphene in modified electrodes promotes electron transfer [12]; this leads to materials with excellent electrocatalytic properties [13]. Agglomeration, however, can occur in graphene during the liquid reduction process [14], which is required for graphene to be functionalized to maintain its inherent properties. Functionalized graphene can retain the excellent properties of graphene, while the functional groups may impart graphene with additional properties [15]. Because of their wide range of solubilities and the introduction of surface charge, ionic liquid-functionalized graphene (IL-graphene) sheets were prepared [16], and the materials showed good dispersibility and long-term stability in various solvents. In addition, IL-graphene based electrochemical sensors have been widely reported in the literature for detecting various types of compounds, such as nitrite [17], NADH [18], hydrogen peroxide [19], and glucose [20].

The deposition of metal or metallic oxide nanomaterial on graphene or graphene oxide (GO) can greatly increase the spac-

ing of layers to improve the dispersibility of graphene and also add the characteristics of a metal composite material [21]. Manganese dioxide (MnO_2) nanomaterial is widely used in electrochemistry because of its superior conductivity, electrochemical performance, and relatively high potential [22]. MnO_2 is often used together with carbon materials such as carbon nanotubes [23], graphene [24], and GO [25], which enhance MnO_2 activity and stability; moreover, a synergistic effect on the electrochemical performance of the nanomaterials is also observed. Lee and coworkers reported a template-free and simple synthesis process for flexible reduced graphene oxide (RGO)/ MnO_2 paper electrodes [26]. The electrochemical capacitors were fabricated with RGO/ MnO_2 and had an areal capacitance of 897 mF cm^{-2} , an energy density of $11.5 \mu\text{Wh cm}^{-2}$, and a capacitance retention of 84% over 3600 cycles. Despite these promising results, there are currently relatively few studies on GO and MnO_2 nanocomposites for electrochemical biosensors [27,28].

In this paper, we combined IL-graphene and MnO_2 nanosheets to fabricate an electrode which could be used as effective sensor for TP electroanalysis. Combining the benefits of IL-graphene and MnO_2 nanosheets for electrochemical sensing applications, a remarkable synergistic increase of the electrochemical performance was achieved. The electrochemical properties and the pH effect of the sensing platform were evaluated using electrochemical techniques. The results revealed that the MnO_2 nanosheets/IL-graphene/GCE had excellent electrocatalytic activity toward TP oxidation. TP concentrations lower than micromolar could be detected with the prepared electrochemical sensor.

2. Experimental

2.1. Chemicals and materials

GO was purchased from Nanjing XFNano Materials Technology Company (Nanjing, China). TP, 1-methylimidazole, 2-bromoethylamine hydrobromide, manganese chloride tetrahydrate, tetramethyl ammonium, and hydrogen peroxide were obtained from Sigma (Shanghai, China). $\text{K}_3\text{Fe}(\text{CN})_6$, $\text{K}_4\text{Fe}(\text{CN})_6$, KCl, and acetic acid were purchased from Sinopharm Chemical Reagent Co., Ltd (Beijing, China). All reagents were analytical grade and used as received. Nanopure deionized and distilled water ($18.2 \text{ M}\Omega \text{ cm}^{-1}$) was used in all of the experiments.

2.2. Apparatus

Cyclic voltammetry (CV) and differential pulse voltammetry (DPV) were performed on a CHI660D electrochemical system (Chenhua Instruments, Shanghai, China) equipped with a personal computer for data storage and processing. The measuring unit was a conventional three-electrode system, with a GCE as the working electrode, an Ag/AgCl/KCl (saturated) electrode as the reference, and a platinum wire as the counter electrode. Transmission electron microscopy (TEM, JEOL 2010F, 200 kV) was used to study the morphology and microstructure of MnO_2 nanosheets. Scanning electron microscopy (SEM) was performed on an S-4800 electron microscope (Hitachi, Ltd., Japan). All of the experiments were conducted at room temperature.

2.3. Preparation procedure

IL-graphene was prepared according to Niu's method [29], while MnO_2 nanosheets were prepared from manganese chloride and hydrogen peroxide [30]. Tetramethyl ammonium solution (12 mL, 1.0 M in water) mixed with hydrogen peroxide (2 mL, 30 wt% in H_2O) was added to the aqueous solution (10 mL) and contained 0.563 g manganese chloride tetrahydrate within 15 s. The

Scheme 1. Schematic illustration of the enhanced electrochemical detection strategy for TP based on MnO_2 nanosheets/IL-graphene modified on the GCE.

resulting dark brown suspension liquid was stirred over night at room temperature. After washing with water three times, MnO_2 nanosheets were obtained. To calculate the concentration of the MnO_2 nanosheets in water, the absorption spectra at 380 nm were measured, and the concentration was calculated using the Beer-Lambert Law. The molar extinction coefficient was $9.6 \times 10^3 \text{ M}^{-1} \text{ cm}^{-1}$ [31].

The prepared IL-graphene (1 mg mL^{-1}) was mixed with MnO_2 nanosheets (20.8 mM) in a 1:1 vol ratio. The solution was sonicated using ultrasound to obtain a homogeneous suspension. The composite was then washed with water three times, and MnO_2 nanosheets/IL-graphene was obtained.

2.4. Preparation of the modified electrode

First, the GCE was polished to a mirror-like surface using $0.3 \mu\text{m}$ and $0.05 \mu\text{m}$ γ -alumina slurries. The GCE was successively washed with ethanol and water in an ultrasonic bath and dried in air before use. $5 \mu\text{L}$ of the MnO_2 nanosheets/IL-graphene solution was dripped onto the surface of the GCE and slowly dried in ambient conditions to form the MnO_2 nanosheets/IL-graphene-modified GCE (MnO_2 nanosheets/IL-graphene/GCE). This was then rinsed with water for the physical removal of the adsorbed species before use. The TP sensing strategy is illustrated in Scheme 1. CV was performed to characterize the different modified electrodes in 0.1 M acetate buffer solutions or in a $1.0 \text{ mM K}_3[\text{Fe}(\text{CN})_6]/\text{K}_4[\text{Fe}(\text{CN})_6]$ (1:1) solution containing 0.1 M KCl. Finally, the DPV signals were recorded in the range of 0.6 V to 1.6 V (increment: 0.005 V; amplitude: 0.05 V; pulse width: 0.1 s; sampling width: 0.02; pulse period: 0.1 s). In all of the electrochemical experiments, the soaking time before measurement was 2 s.

3. Results and discussion

3.1. Morphology and characterization

The stability of MnO_2 nanosheets is shown in Fig. S1A. After standing statically for 15 h, the suspension solutions of MnO_2 nanosheets were unchanged (Fig. S1A picture b), which indicated that the stability was excellent. The morphology of the MnO_2 nanosheets was examined using TEM. Fig. S1B shows the typical TEM images of the MnO_2 nanosheets, and the flexible flake-like morphology is evident. The surface morphologies of the different nanomaterials were investigated using SEM. Fig. 1 shows the typical image of IL-graphene (A and B), MnO_2 nanosheets (C and D), and MnO_2 nanosheets/IL-graphene (E and F). IL-graphene showed the characteristic crumpled and wrinkled structure (Fig. 1A and B), and the MnO_2 nanosheets showed a lamellar and plate-like structures (Fig. 1C and D). After mixing the two materials together, the MnO_2 nanosheets/IL-graphene nanocomposite presented a uni-

Fig. 1. SEM image of the IL-graphene (A and B), MnO₂ nanosheets (C and D), and MnO₂ nanosheets/IL-graphene (E and F) with different magnifications.

form distribution structure, indicating the successful attachment of the materials (Fig. 1E and F). The FT-IR spectrum of IL-graphene is shown in Fig. S2. The peaks at 2935 cm^{-1} and 2843 cm^{-1} (b and d) were ascribed to the $\text{CH}_3(\text{N})$ and $\text{CH}_2(\text{N})$ stretching vibrations, respectively. In particular, the stretching vibration of the C–N bonds in the imidazole ring was clearly observed at 1637 cm^{-1} [32], further indicating the successful synthesis of the MnO₂ nanosheets/IL-graphene. The MnO₂ nanosheets/IL-graphene was further examined using X-ray photo-electron spectroscopy (XPS), and the results are shown in Fig. S3. The XPS spectrum (A) showed the presence of four elements: C, N, O, and Mn. The C1s spec-

trum (B) showed three main types of carbon bonds: C–C (284.6 eV), C–N (285.9 eV), and epoxy-carbon (287.7 eV) [33]. In addition, the N1s band appeared at 401.7 eV (Fig. 2C) with a lower binding-energy shoulder at 397.9 eV, which clearly confirmed the presence of IL-graphene. The $\text{Mn}2p_{3/2}$ and $\text{Mn}2p_{1/2}$ spectrum (Fig. S3D) showed the presence of MnO₂ [34]. Fig. S4 shows the Raman spectra of IL-graphene (curve a), the MnO₂ nanosheets (curve b) and the MnO₂ nanosheets/IL-graphene nanocomposite (curve c). The Raman spectrum of IL-graphene exhibited a slightly increased D/G intensity ratio relative to that of GO [33], and this may suggest a decrease in the average size of the sp^2 domains in IL-graphene.

Fig. 2. CV response of the MnO₂ nanosheets/IL-graphene/GCE in acetate buffer solutions (pH 5) at a scan rate of 20 mV s⁻¹.

The Raman spectrum of the MnO₂ nanosheets was not clearly observed, and the Raman spectrum of the MnO₂ nanosheets/IL-graphene did not change compared to IL-graphene, which implied that the structure of IL-graphene did not change in the formation process. Elemental analysis (Table S1) showed that the imidazole cation was synthesized within the surface of GO and still existed after the formation of the nanocomposite.

3.2. Electrochemical behavior of MnO₂ nanosheets/IL-graphene/GCE

The formation of the MnO₂ nanosheets/IL-graphene/GCE composite was also verified by measuring the CV of the modified electrode in an acetate buffer solution (pH 5). As shown in Fig. 2, during the positive potential scan, an oxidation peak was observed at 0.91 V, which can be attributed to the oxidation of Mn²⁺ to Mn⁴⁺ ions. A reduction peak was observed at 0.63 V during the cathodic scan, and this corresponded to the reduction of Mn⁴⁺ back to Mn²⁺ ions. According to the electrochemical-chemical-electrochemical (ECE) mechanism, the oxidation of Mn²⁺ in low acidic or neutral media is given by the equation [35]:

During the fabrication process, investigation of barrier changes on the electrode surface was required. For this purpose, CV measurements of 1.0 mM [Fe(CN)₆]^{3-/4-} solutions were performed using different working electrodes; more specifically, a bare GCE, IL-graphene/GCE, MnO₂ nanosheets/GCE, and MnO₂ nanosheets/IL-graphene/GCE were investigated in an acetate buffer (pH 6.5). As depicted in Fig. 3, the cyclic voltammogram of the bare GCE showed an oxidation peak current of 8.978 μA and a reduction peak of -9.050 μA (curve a). When IL-graphene was immobilized on the same electrode, the oxidation and the reduction currents increased to 11.53 and 12.17 μA respectively (curve b). This was because IL-graphene has an imidazole cation which has the ability to interact with the [Fe(CN)₆]^{3-/4-} ion via strong electrostatic interactions. On the MnO₂ nanosheets/GCE (curve c), there were not well defined oxidation-reduction peaks, because the negative charge of the MnO₂ nanosheets repelled the [Fe(CN)₆]^{3-/4-} anion. However, the oxidation and reduction currents of 9.126 μA and 17.50 μA, respectively, were still observed with the MnO₂ nanosheets/IL-graphene/GCE; this can be ascribed to the uniform distribution structure and consequently to the easier electron transfer at the electrode/solution interface. These data confirmed that the modified sensing interface was successfully developed.

Fig. 3. CVs of 1.0 mM [Fe(CN)₆]^{3-/4-} in 0.1 M KCl recorded using: (a) the bare GCE, (b) the IL-graphene/GCE, (c) the MnO₂ nanosheets/GCE, and (d) the MnO₂ nanosheets/IL-graphene/GCE. The scan rate was 100 mV s⁻¹.

3.3. Effects of scan rate

To investigate the reaction kinetics, the MnO₂ nanosheets/IL-graphene/GCE was scanned using CV at various rates in a 0.1 M acetic acid buffer solution (pH=5), and the results are shown in Fig. 4. As the scan rate increased, the redox peak current increased correspondingly. Moreover, both the cathodic and anodic peak currents increased with an increase in the scan rate from 0.01 to 0.1 V s⁻¹. In addition, there was a linear correlation between the scan sweep rates (ν) and the anode (E_{pa}) and cathode (E_{pc}) peak potentials (see inset of Fig. 4). These results indicate that the electrochemical redox of MnO₂ nanosheets/IL-graphene/GCE behaved as a typical adsorption-controlled process and as a surface-limited reaction. The surface concentration of the electroactive species, Γ , can be calculated from the slope of the plot of I_{pa} vs. scan rate using the following equation [36]:

$$I = n^2 F^2 \nu A \Gamma / 4RT$$

where A is the surface area, and ν is the sweep rate. The value of Γ was calculated to be approximately 2.316×10^{-10} mol cm⁻².

Fig. 4. CV responses of the MnO₂ nanosheets/IL-graphene/GCE in a 0.1 M acetate buffer solution (pH 5) at scan rates (from inner to outer) of: 10, 20, 30, 40, 50, 60, 70, 80, 90, and 100 mV s⁻¹. Inset shows the plot of peak current vs. scan rate.

Fig. 5. CVs of the MnO₂ nanosheets/IL-graphene/GCE in solutions with different pH values from 2 to 7. The scan rate was 100 mV s⁻¹.

3.4. The effect of pH

The electrochemical redox behavior of the MnO₂ nanosheets/IL-graphene/GCE was investigated using CV in different buffering systems, with pH values varying from 2.0 to 7.0, and the results are shown in Fig. 5. The CV curves showed that pH has a significant effect on the electrochemical process. Because MnOOH is unstable in acidic media, the oxidation peak current (oxidation of MnOOH to MnO₂) was largely reduced and nearly disappeared as seen in Fig. 5 (pH = 2). At the same time, as the medium acidity decreased, the oxidation peak currents (*I*_{pa}) increased. The maximum current was observed with a pH of 5, and for higher pH values, the current decreased. Based on these results, a pH 5 buffer was chosen as the optimal pH value in this experiment.

3.5. Amperometric sensing of TP

To investigate the potential electrocatalytic activity of the MnO₂ nanosheets/IL-graphene/GCE system for TP oxidation, DPV was performed. Electrochemical experiments were carried out both in the absence and in the presence of TP. As shown in Fig. 6, the electrochemical properties of GCE and the MnO₂ nanosheets/GCE were compared with those of the modified electrode in a 0.1 M acetic

Fig. 6. DPVs recorded using the bare GCE (a and d), the MnO₂ nanosheets/GCE (b and e), and the MnO₂ nanosheets/IL-graphene/GCE (c and f) electrodes in the absence (a, b, and c) and presence (d, e, and f) of 1 mM TP in a 0.1 M acetate buffer solution (pH 5).

acid buffer (pH = 5) in the absence and in presence of TP (1 mM concentration). With the bare GCE and the MnO₂ nanosheets/GCE oxidation peaks of 1.581 μA at 1.12 V and 0.3638 μA at 1.08 V were detected with the 1 mM TP solution, and the current increased to 3.143 μA when the modified electrode was employed. No obvious signal was observed with either electrode in the absence of TP. The significant increase in the current was due to the improved electrocatalytic properties of the MnO₂ nanosheets. Indeed, the superior catalytic properties of the MnO₂ nanosheets were indicated by the reduced overpotential and the enhanced TP oxidation signal. These data showed that such material was suitable for the electron transfer between TP and the working electrode; moreover, it promoted the electrochemical regeneration of the TP electron exchange.

Based on the obtained results, a possible reaction mechanism for the TP oxidation with MnO₂ nanosheets is shown below [36]:

To optimize the electrocatalytic response for TP oxidation, the effect of pH was investigated. DPV was performed in acetic acid buffer at various pH with 5 mM TP, as shown in Fig. 7. The oxidation between TP and MnO₂ was significantly affected by pH. The MnO₂ nanosheets/IL-graphene/GCE showed electrocatalytic activity for pH between 3 and 8. The maximum TP oxidation current was observed at pH 3; the peak potential, however, was too high at this pH. The second highest maximum current was obtained with pH 5. Therefore, pH 5 was considered the optimum pH value for TP detection.

Additionally, the DPV response of the MnO₂ nanosheets/IL-graphene/GCE electrode was measured with different concentrations of TP (Fig. 8). As shown in the figure, a well-defined peak was observed with the successive addition of 1 μM TP, which demonstrated that the MnO₂ nanosheets on the modified electrode were stable and efficient catalysts. Under the optimal conditions, the TP oxidation peak current (*I*_{pa}) increased with concentration in the range from 1 μM to 220 μM. The DPV current maximum shown in Fig. 8 was fitted using linear regression equations. Two fittings were performed depending on the TP concentration range: one for TP content between 1 and 10 μM, and one for TP content between 10 and 220 μM. According to this, the detection resolution limit was 0.1 μM (S/N = 3). To further confirm the advantages of the MnO₂ nanosheets/IL-graphene/GCE for TP determination, Table S2 shows the comparison of this method with other electrochemical methods and illustrates that MnO₂ nanosheets/IL-graphene/GCE had excellent sensitivity and a wide linear range.

To evaluate the potential effect of foreign species on the determination of 50 μM TP, a systematic study was carried out under the above optimized conditions. The peak currents of TP in the absence and presence of foreign species were measured using DPV. The results are listed in Table S3. It was found that 10-fold concentrations of Fe³⁺, Ba²⁺, Al³⁺, Ni²⁺, Cu²⁺, CO₃²⁻, PO₄³⁻, and NO₃⁻; 2-fold concentrations of phenol, hydroquinone, catechol, resorcinol, guanine, and caffeine did not interfere with the oxidation signal of TP (signal change below 5%).

3.6. Application of the probe

The use of the proposed method in real sample analysis was also investigated using direct analysis of TP in a commercially available drug tablet (25.0 mg per tablet). The effect of TP concentration was investigated using DPV with 5 repeated responses. The samples were spiked with a specified concentration of TP, and using the

Fig. 8. DPV of the MnO₂ nanosheets/IL-graphene/GCE in 0.1 M acetate buffer solution (pH 5) with increasing concentrations of TP. (A from bottom to top: 1, 2, 3, 4, 5, and 6 μM and B from bottom to top: 10, 50, 70, 100, 150, 200, and 220 μM.).

Table 1

Method recoveries for TP determination in a commercially available drug (25.0 mg per tablet, Mr_{TP} = 180.16, n = 5).

Sample (μM)	Found (μM)	Spiked (μM)	Total Found (μM)	Recovery (%)	RSD (%)
5	5.04	10	14.96	99.7	1.2
10	9.98	10	20.05	100.4	1.6
50	50.2	50	100.6	100.8	2.1
100	99.1	50	149.0	99.0	2.9

standard addition method, TP concentration measurements were made in the recovery rate of the spiked samples. The results are listed in Table 1 and demonstrate that the MnO₂ nanosheets/IL-graphene/GCE might be a promising system for detecting TP in real samples.

4. Conclusions

In summary, a novel electrochemical system was proposed based on a new nanocomposite made of MnO₂ nanosheets and IL-graphene as modifiers on the GCE. The MnO₂ nanosheets/IL-graphene/GCE exhibited excellent redox response and effective electrocatalytic activity towards TP oxidation. The electrocatalytic activity of the MnO₂ nanosheets led to greatly improved electrochemical sensitivity in TP detection using the DPV technique. The detection resolution limit of the proposed sensor was 0.1 μM in a concentration range from 1 μM to 220 μM. Finally, the MnO₂ nanosheets/IL-graphene/GCE was also used to detect TP content in drug samples with satisfactory results. This study offers a new approach for TP sensing and also provides new insight into the application of MnO₂ nanosheets in electrochemical sensors.

Biographies

Xuming Zhuang received his PhD in analytical chemistry from the Department of Chemistry of Shandong University, Jinan, in 2013. In the same year, he joined in College of Chemistry and Chemical Engineering, Yantai University, as a lecturer. His current research interest focuses on preparation of novel electrochemical biosensors and applications to in vivo analysis.

Dandan Chen received her BS degree from College of Chemistry and Chemical Engineering, Yantai University, in 2015. She is studying for her master degree in College of Chemistry and Chemical Engineering, Yantai University. Her current research interest is the electrochemical biosensor and detection of small biomolecules.

Shengnan Wang received her BS degree from College of Chemistry and Chemical Engineering, Yantai University, in 2015. She is studying for her master degree in Department of Chemistry, College of Science, Shanghai University. Her current research interest is the proton exchange membrane (PEM), which is the core part of the PEMFCs and improving its comprehensive performances.

Huitao Liu received her PhD degree in analytical chemistry from Lanzhou University, Lanzhou, in 2000. After a year of postdoctoral experience at the Department of Chemistry, National Sun Yat-sen University, Kaohsiung, Taiwan, she joined as a professor, College of Chemistry and Chemical Engineering, Yantai University. Her research interests include the development of food and medicine analysis methods using capillary electrophoresis and high performance liquid chromatography; preparation of novel functionalized nanomaterials and their application in analytical chemistry.

Lingxin Chen has been a professor at Yantai Institute of Coastal Zone Research, Chinese Academy of Sciences, since 2009. He obtained his Ph.D. in analytical chemistry at Dalian Institute of Chemical Physics, Chinese Academy of Sciences, in 2003. During 2004–2009, he worked at Department of Chemistry, Tsinghua University, and Department of Applied Chemistry, Hanyang University, respectively. His research interests include the studies of novel properties of materials such as functionalized nanoparticles & functional probe molecules for developing nanoscale biochemical analysis methods and molecular imprinting-based sample pretreatment technology.
