ABSTRACT

In this work, silver nanoparticles (AgNPs) were self-assembled on the micro-needle electrode (MNE) with the help of chitosan (CTS) and polyvinylpyrrolidone (PVP) and used for the amperometric (i-t) determination of nitrate (NO_3^-) in seawater samples. CTS/PVP was electrodeposited on the MNE surface to improve the conductivity and specific surface area of the MNE, and to provide reduction conditions needed for Ag^+ reduction and strong binding affinity for combination of AgNPs which had excellent catalytic activity for NO_3^- . AgNPs were self-assembled uniformly on the surface of MNE with the diameter of about 150–400 nm. Thanks to the unique aciform structure of MNE, the outstanding adhesion ability of CTS/PVP, and the excellent electrocatalytic ability of AgNPs, the so-prepared AgNPs/CTS/PVP/MNE showed significantly improved performance and stability for the amperometric determination of NO_3^- . Under the optimal conditions, the AgNPs/CTS/PVP/MNE was found to have a wide linear range (5–2000 μM) and a low limit of detection (1.2 μM). Furthermore, the AgNPs/CTS/PVP/MNE was successfully used for the direct determination of NO_3^- in coastal seawater samples with satisfactory results.

1. Introduction

Nitrates (NO_3^-) are naturally present in soil, water, and food, which has important effects on environmental and human health [1,2]. In marine environment, the photosynthesis of phytoplankton is largely controlled by N nutrients including NO_3^- , nitrite, and ammonium [3]. NO_3^- is of particular interest because it represents the main source of N in marine ecosystems and acts as a marker for water quality [4]. The seawater environment with excessive NO_3^- concentration will break the balance of local marine ecosystems, leading to hyper proliferation of algae, generation of red tides, deterioration of water quality, and destruction of biodiversity [5]. Moreover, the concentration of NO_3^- is easy to change with the external environment. Therefore, to understand

the N cycle and dynamics of marine ecosystems, it is necessary to determine the concentration of NO_3^- in seawater rapidly and accurately.

To date, a wide range of analytical methods have been developed for determination of NO_3^- . The most commonly used techniques include ion-exchange chromatography [6], capillary electrophoresis [7], colorimetry [8], UV spectroscopy [9], reflectance mid-infrared spectroscopy [10], and high-performance liquid chromatography [11]. Although many of these methods are sensitive and accurate, most of them require sample pretreatment and/or pre-concentration which are relatively time-consuming, fiddly and costly [12]. Electrochemical methods represent an interesting alternative with the advantages of low cost, ease of use, low energy requirements and simple procedures [13]. Furthermore, it presents the possibility to build portable systems that are

compatible either for laboratory or on-site measurements. Recently, many electrochemical sensors based on different electrodes have been prepared for the determination of NO_3^- . Different electrode materials including copper [14,15], precious metals [16], bimetallic alloys [17,18], and base metals [19–21] have been investigated for voltammetric and amperometric analysis of NO_3^- . For example, the Cu microsphere modified electrode presented in our previous work could be successfully used for the determination of NO_3^- in river water samples [12]. However, these nanomaterials-based electrodes are usually applied in the environment with pH value below 3.0. Obviously, it is not suitable for the direct detection of NO_3^- in natural seawater with pH about 8.0. Therefore, there is still an urgent need for novel and effective electrodes for direct detection NO_3^- in seawater.

Ag nanoparticles (AgNPs), one of the popular metal nanomaterials, have several advantages such as small size, large surface area, high surface activity and excellent catalytic performance, and have been widely assembled on electrodes to act as electro-catalytic material for various reactions [22–24]. Importantly, AgNPs also exhibit an extremely fast response for the electrochemical reduction of NO_3^- in natural water with no need to change the pH value [25]. Acupuncture which is considered as a pivotal component of Eastern medicine has the functions of relieving pain, warming the meridians and promoting the blood flow through the application of an acupuncture needle into the physical body of the patient [26,27]. The stainless steel acupuncture needle has the properties of conductivity, small size, large specific surface area, and easy operation, which makes it a potential electrode material for electrochemical sensing applications. Therefore, micro-needle electrode (MNE) made of stainless steel acupuncture needle provides a promising electrochemical sensing platform with large specific surface area for the combination of functional nanomaterials for different small biomolecules and inorganic ions [28,29]. To achieve the modification of AgNPs on MNE, surface modification is clearly needed because of the smooth surface of stainless steel MNE [24].

As a natural biopolymer, Chitosan (CTS) exhibits excellent properties such as film-forming ability, biocompatibility, multiple functional groups, and pH-dependent solubility in aqueous media [30]. As reported, CTS can form stable membrane with conducting materials and enhance their conductivity [31,32]. Many kinds of materials such as graphene oxide (GO), carbon nanotubes (CNTs), Ag, Si, and Cu have ever been reported to combine with CTS due to its reducibility, abundant functional groups, and film-forming ability. These properties make CTS a widely used immobilization agent for different nanomaterials to fabricate novel electrochemical sensors. Moreover, the functional groups of CTS can reduce Ag^+ to Ag^0 , which looks like Tollen reaction and provides conditions for the self-assembly of AgNPs on the electrode [33,34]. Polyvinylpyrrolidone (PVP) is a well-known macromolecule surfactant with advantages of low toxicity, biocompatibility, high surface activity, and strong adsorption ability [35]. In addition, it is known that PVP is one of the attractive polymers to immobilize inorganic

nanoparticles due to its strong affinity of pyridyl group to metals and ability to undergo hydrogen bonding with polar species [36]. Furthermore, the composite of CTS and PVP (CTS/PVP) can not only protect the electrode, but also enhance the bonding ability with metal nanomaterials [37,38].

In this work, AgNPs were self-assembled on the MNE which was surface modified with CTS/PVP to fabricate the AgNPs/CTS/PVP/MNE for amperometric determination of NO_3^- in seawater. As the conductive polymer, reducing agent, and adhesion agent, CTS/PVP film offered a lot of binding sites for the combination of AgNPs which had excellent catalytic performance for the electrochemical reduction of NO_3^- . The so-prepared AgNPs/CTS/PVP/MNE exhibited outstanding performance for the amperometric detection of NO_3^- . Furthermore, the AgNPs/CTS/PVP/MNE was successfully used for the direct detection of NO_3^- in coastal seawater samples at natural pH condition.

2. Experimental

2.1. Materials and reagents

Silver nitrate (AgNO_3), sodium nitrate (NaNO_3), ethanol ($\text{CH}_3\text{CH}_2\text{OH}$), acetic acid (HAc), ammonium hydroxide, PVP, and CTS were purchased from Sinopharm Chemical Reagent Co. Ltd. (Shanghai, China). Unless otherwise stated, phosphate buffer (pH 7.0) was used as the supporting electrolyte for electrochemical experiments. Deionized water (18.2 M Ω cm specific resistance) obtained from Pall Cascade laboratory water system was used throughout. All chemicals were analytical reagents and used without further purification. Stainless steel acupuncture needles (Suzhou Medical Appliance Factory Co., Ltd, China) were used as the electrode substrates. Silicone rubber purchased from Liyang Kangda Chemical Co. Ltd., China was adopted as the sealant.

2.2. Apparatus

The morphologies of the bare and modified MNEs were characterized by scanning electron microscopy (SEM, Hitachi S-4800 microscope, Japan). X-ray photoelectron spectroscopy (XPS) was carried out on a Thermo ESCALAB 250XI (America). All the electrochemical experiments including cyclic voltammetry (CV) and amperometric i-t were performed on a CHI660E electrochemical workstation (CH Instruments, Inc., Shanghai, China). The modified MNE served as the working electrode, with Ag/AgCl (3.0 M KCl) and platinum foil serving as the reference and counter electrode, respectively. All potentials were measured with respect to the Ag/AgCl reference electrode.

2.3. Preparation of the AgNPs/CTS/PVP/MNE

The procedure for the fabrication of AgNPs/CTS/PVP/MNE was

Fig. 1. SEM images of the MNE (A), CTS/PVP/MNE (B), and AgNPs/CTS/PVP/MNE (C, D).

illustrated in Scheme 1. Firstly, the MNE was manufactured by stainless steel acupuncture needles as described in our previous works [12,39]. Simply, the needle body part of the acupuncture needle was insulated and sealed with silicone rubber; leaving the needle tip about 1 mm and needle handle out for the sensing surface and electrode wire, respectively. Secondly, the cleaning of the stainless steel acupuncture needle (diameter of 0.25 mm, length of 60 mm) was conducted with the help of sonication in ethanol and deionized water for 5 min, respectively. Then the CTS/PVP film was deposited on the MNE surface to prepare the CTS/PVP modified MNE (CTS/PVP/MNE) by electrodeposition in the mixed solution of 0.1 mg/ml PVP and CTS (0.1 M HAc) at the potential of -2 V for 200 s. Lastly, the CTS/PVP/MNE was put into the AgNO_3 solution for 5 min to achieve the self-assembly of AgNPs on the CTS/PVP/MNE. After careful cleaning and drying at room temperature, the AgNPs/CTS/PVP/MNE was obtained eventually.

2.4. Electrochemical analysis procedure

The CV plots were obtained in PBS solution (pH 7) in the range of -0.8 to 0.4 V at the scan rate of 100 mV/s. The current responses of NO_3^- on different MNEs were investigated by amperometric *i-t* technique using the following parameters: potential of -1.1 V, pulse period of 0.5 s, and quiet time of 2 s.

3. Results and discussion

3.1. Characterization of the AgNPs/CTS/PVP/MNE

To investigate the surface morphology of AgNPs/CTS/PVP/MNE, SEM characterization was conducted (Fig. 1). It can be seen clearly that the surface of the bare MNE was very smooth (Fig. 1A). It has been described in our previous works that the smooth surface provided few binding sites for functional nanomaterials [39]. As shown in Fig. 1B, a uniform and dense film deposited on MNE surface after the modification of PVP and CTS, which made the electrode surface more rough. The existence of CTS/PVP could not only improve the conductivity, but also increase the specific surface area and active binding sites of the electrode. Importantly, it was also used as reducing agent for the self-assembly of AgNPs and adhesion agent for the immobilization of AgNPs. As shown in Fig. 1C and D, AgNPs were distributed uniformly on

Fig. 2. Amperometric *i-t* curves of the bare MNE (a), CTS/PVP/MNE (b), and AgNPs/CTS/PVP/MNE (c) in 0.1 M NaCl solution with successive addition of the same concentration of NO_3^- .

the surface of MNE with the diameter of about 150 to 400 nm after the self-assembly of AgNPs. AgNPs were successfully self-assembled and immobilized on the electrode because of the reduction capacity of CTS and strong affinity of PVP. The results of SEM characterization demonstrated that both CTS/PVP film and AgNPs were successfully modified on the MNE.

Subsequently, the AgNPs/CTS/PVP/MNE was characterized by means of XPS and CV. The XPS spectra of different electrodes were shown in Fig. S1. The presence of N and Ag signals proves the successful modification of CTS/PVP and AgNPs on the AgNPs/CTS/PVP/MNE. In addition, the Ag peaks of AgNPs/CTS/PVP/MNE shifted to higher binding energy, which might be caused by the strong interaction between the O of carbonyl group ($\text{C}=\text{O}$) in PVP and the AgNPs. The electrochemical properties of AgNPs/CTS/PVP/MNE were further investigated by CV (Fig. S2). The results showed that AgNPs and CTS/PVP were modified successfully on MNE, which improved the conductivity and specific surface area of the electrode. The Electrode kinetics information was obtained by the CV behavior of AgNPs/CTS/PVP/MNE

Fig. 3. Amperometric i-t curve obtained on the AgNPs/CTS/PVP/MNE with successive addition of NO_3^- from 0.005 to 2 mM in 0.1 M NaCl solution. Inset shows the corresponding calibration curve.

in 0.1 M NaCl solution containing 1 mM NO_3^- at different scan rates (Fig. S3). The current response had a linear relationship with the square root of the scan rates, showing that the reduction of NO_3^- on the AgNPs/CTS/PVP/MNE was a diffusion-controlled electrode process.

3.2. Electrochemical responses of AgNPs/CTS/PVP/MNE to NO_3^-

To explore the electrocatalytic reduction performance of CTS/PVP/AgNPs/MNE to NO_3^- , the current responses of MNE (a), CTS/PVP/MNE (b), and AgNPs/CTS/PVP/MNE (c) were compared by amperometric i-t method in 0.1 M NaCl solution with the potential of -1.1 V (Fig. 2). It can be seen that there was no response signal of NO_3^- could be obtained on the bare MNE. A much small cathodic response to NO_3^- (0.12 μA) could be detected by the CTS/PVP/MNE, which indicated CTS/PVP played a limited role for the amperometric detection of NO_3^- . Although the promotion effect of CTS/PVP was limited, it provided a large specific surface area and improved conductivity. PVP has the advantages of high surface activity and strong adsorption capacity, which are helpful for the detection of NO_3^- [35]. Compared to MNE and CTS/PVP/MNE, the AgNPs/CTS/PVP/MNE showed the best performance for NO_3^- detection (2.6 μA) thanks to the excellent catalytic performance of AgNPs. CTS can form stable conductive membrane with PVP and provide conditions for the self-assembly of AgNPs on the MNE. In addition, due to the strong affinity between AgNPs and pyridyl group of PVP which formed film with CTS, the stability of the AgNPs/CTS/PVP/MNE is significantly improved. So, the enhanced performance of AgNPs/CTS/PVP/MNE was caused by the combination of the excellent properties of CTS/PVP and AgNPs.

3.3. Optimization for NO_3^- determination with the AgNPs/CTS/PVP/MNE

The following parameters were optimized for the amperometric detection of NO_3^- : mass ratio of CTS to PVP (Fig. S4A); deposition time of CTS/PVP (Fig. S4B); self-assembly time of the AgNPs (Fig. S4C); Respective data and Figures were given in the Supporting Information. The following experimental conditions were found to give best results: mass ratio of CTS to PVP (1:1); deposition time of CTS/PVP (400 s); self-assembly time of the AgNPs (5 min).

3.4. Calibration curve

Fig. 3 shows the calibration curve and corresponding amperometric i-t plots obtained at AgNPs/CTS/PVP/MNE in 0.1 M NaCl solution under

Table 1

Comparison of AgNPs/CTS/PVP/MNE with previously reported electrodes for NO_3^- determination.

Electrode	Method	Linear range (mM)	Detection limit (μM)	Ref.
Cu	DPV	0.1–2.5	11.0	[40]
L-SCMNPs-CPEs	SWV	0.10–1.982	87.0	[41]
Pd/Sn/microband electrode	LSV	0.016–0.333	–	[42]

Ag/GCE	i-t	0.01–5	4	[46]
AgNPs/CTS/PVP/MNE	i-t	0.005–2	1.2	This work

L-SCMNPs, 3,6-bis(2-[2-sulfanyl-ethylimino-methyl]-4-(4-nitro-phenylazo)-phenol)pyridazine coated $\text{SiO}_2/\text{Fe}_3\text{O}_4$; CPEs, carbon paste electrodes; CNT, carbon nanotubes; PPy, polypyrrole; AgNS, Ag nanostructures; UMEs, ultra-microelectrodes; GCE, glassy carbon electrode; DPV, differential pulse voltammetry; SWV, square wave voltammetry; LSV, linear sweep voltammogram.

the optimal conditions described above. The current response was linear with the concentration of NO_3^- ranging from 0.005 to 2 mM. The regression equation was $I = 0.04C + 13.39$ ($R^2 = 0.996$), where I represented the current in μA , and C was NO_3^- concentration in mM. The detection limit (LOD) of AgNPs/CTS/PVP/MNE for NO_3^- determination was calculated as 1.2 μM under the optimal conditions. The comparison of the AgNPs/CTS/PVP/MNE fabricated here with other electrodes published previously for NO_3^- determination is presented in Table 1. It can be seen that when compared with other electrodes, the so-fabricated AgNPs/CTS/PVP/MNE showed superior performance for NO_3^- determination with higher sensitivity and wider linear range.

3.5. Repeatability, selectivity and stability

To investigate the suitability of the AgNPs/CTS/PVP/MNE for NO_3^- determination in complex water samples, its repeatability, selectivity and stability were all evaluated. The repeatability of the AgNPs/CTS/PVP/MNE was evaluated by detecting 1 mM NO_3^- at the same electrode for fifty measurements, and the relative standard deviation (RSD) was calculated to be 3.1%, indicating a good repeatability of the AgNPs/CTS/PVP/MNE. The effects of possible interfering species for the amperometric determination of NO_3^- were investigated by adding foreign species into the 0.1 M NaCl solution containing 1 mM NO_3^- under the optimal conditions. The results showed that 30-fold Na^+ , Mg^{2+} , Cr^{3+} and Cu^{2+} , 10-fold Zn^{2+} , As^{3+} and 4-nitrophenol, and equivalent Fe^{2+} and Cl^- did not affect the determination of NO_3^- ($<5\%$ of response current change). The CV curves of AgNPs/CTS/PVP/MNE in 1 mM NO_3^- solution with and without typical reducible species including Cu^{2+} (30 mM) and 4-nitrophenol (10 mM) were presented in Fig. S5. These results showed that the AgNPs/CTS/PVP/MNE proposed here had a good selectivity for NO_3^- determination. Additionally, the stability of the AgNPs/CTS/PVP/MNE was investigated by measuring the current response of 1 mM NO_3^- every day with the same AgNPs/CTS/PVP/MNE. There was no obvious decrease of the current response after 15 days, indicating the good stability of the AgNPs/CTS/PVP/MNE.

3.6. Practical application for NO_3^- determination in seawater

To evaluate the practical application of the so-fabricated AgNPs/CTS/PVP/MNE, it was used for the determination of NO_3^- in real coastal seawater samples. In July 2019, seawater samples were collected at 9 stations at the Yellow River Estuary, DongYing, China. The sampling locations and corresponding latitude and longitude information of each

Table 2

Comparison of the results for NO₃⁻ determination in seawater samples by AgNPs/CTS/PVP/MNE and ion chromatography (IC) method (n = 3).

Seawater samples	Detected by this method (μM)	Detected by IC (μM)
S1	143.8 ± 4.6	148.9
S2	167.6 ± 7.3	163.4
S3	241.2 ± 10.5	245.5
S4	319.4 ± 12.2	318.6
S5	276.2 ± 11.7	286.1
S6	341.1 ± 15.3	338.8
S7	328.2 ± 13.6	330.7
S8	383.8 ± 17.1	392.0

location was presented in Fig S6 and Table S1 respectively. After collection, the samples were filtered (0.45 μm membrane) and kept in a refrigerator at 4 °C until detection. Before determination, all the samples were diluted ten times and determined directly without pH adjustment. The concentrations of NO₃⁻ in the real seawater samples were determined by standard addition method. As shown in Table 2, the results obtained with the AgNPs/CTS/PVP/MNE were in agreement with that detected by ion chromatography (IC) method. The results indicated that the AgNPs/CTS/PVP/MNE fabricated here might be a reliable and suitable candidate for the direct determination of NO₃⁻ in seawater.

4. Conclusions

In summary, a novel and effective AgNPs/CTS/PVP/MNE was fabricated for sensitive and direct determination of NO₃⁻ in seawater. The CTS/PVP not only improved the conductivity and specific surface area of the MNE, but also provided the reduction conditions needed for Ag⁺ reduction and strong binding affinity for combination of AgNPs which had excellent catalytic activity for NO₃⁻. The combined outstanding properties of MNE, CTS/PVP and AgNPs made the AgNPs/CTS/PVP/MNE a promising sensor for the direct determination of NO₃⁻ in seawater.
