Hydrophilic interaction liquid chromatography
Chromatographic stationary phases
Alkaloids and benzoic acids

A B S T R A C T

Hydrophilic interaction liquid chromatography (HILIC) plays an important role in the analysis of compounds having high polarity. In this study, fosfomycin (F) was chosen as a new end-capping reagent, owing to the facile hydrolysis reaction of its epoxy group. Zirconia coated silica (ZrO\textsubscript{2}/SiO\textsubscript{2}) materials having good chemical and physical stability were prepared. D-glucose-6-phosphate (G) and D-fructose1,6-bisphosphate (FDP) were modified onto the inner and outer surfaces of the ZrO\textsubscript{2}/SiO\textsubscript{2} microbeads. The new end-capping reagent (F) was then bonded onto the surface of the modified material through Lewis acid-base interactions. The properties (morphology, Zr content, pore size, pore volume, and carbon content) of the stationary phases (SPs) were characterized. Finally, the resulting end-capped SPs were employed to separate alkaloids and benzoic acids. Multiple interactions, including HILIC, electrostatic repulsion, ion exchange and hydrogen bonding, contributed to the retention of the analytes on the SPs. On the F-FDP-ZrO\textsubscript{2}/SiO\textsubscript{2} column, a theoretical plate number of 31,700 plates/m and an asymmetry factor of 1.63 were achieved for berberine, exhibiting good chromatographic performance. Furthermore, the FDP-ZrO\textsubscript{2}/SiO\textsubscript{2} column showed good acid-base stability and good potential for the analysis of benzoic acid in Sprite and ginsenoside separations. Thus, the results indicated the significant potential of using F as an end-capping reagent.

1. Introduction

High performance liquid chromatography (HPLC) is one of the most widely used and effective tools in various research fields such as food analysis \cite{1,2}, pharmaceutical analysis \cite{3–5}, biological sample analysis \cite{6}, and environmental science \cite{7,8}. Chromatographic columns are the core of HPLC, with chromatographic stationary phases (SPs) being their key component. Thus, the design, synthesis, and evaluation of novel SPs exhibiting good performance have garnered significant research interest \cite{9–12}. Recently, metal oxide coated silica materials (such as Al\textsubscript{2}O\textsubscript{3}/SiO\textsubscript{2} \cite{13}, TiO\textsubscript{2}/SiO\textsubscript{2} SPs \cite{14}, and ZrO\textsubscript{2}/SiO\textsubscript{2} microbeads \cite{15}) have exhibited considerable application potential in HPLC and sample preparation \cite{16}. In particular, ZrO\textsubscript{2} and ZrO\textsubscript{2}/SiO\textsubscript{2} based materials have received considerable attention as SPs for HPLC owing to their significant mechanical, chemical (1 < pH < 14), and thermal (>200 °C) stabilities \cite{17,18}. Moreover, ZrO\textsubscript{2}/SiO\textsubscript{2} based SPs show substantial potential for the separation of polar or weakly polar basic or acidic compounds \cite{14}.

However, ZrO\textsubscript{2}/SiO\textsubscript{2} materials cannot be modified in the same manner as silica because of the poor stability of Zr-C and Zr-O-Si bonds in aqueous solutions \cite{17,19}. Currently, many types of electronegative inorganic and organic phosphates have been modified on the surface of ZrO\textsubscript{2} based materials through Lewis acid-base reactions \cite{17,18,20,21}. He et al. \cite{20} employed n-octadecylphosphonic acid as a derivatization reagent and modified it onto the surface of MgO-ZrO\textsubscript{2} materials, which were then end-capped by trimethylchlorosilane to enhance their chromatographic separation properties. The end-capped SPs exhibited better chromatographic performance towards basic compounds than the SPs without the end-capping reaction. Wang et al. \cite{18} prepared adenosine-bonded ZrO\textsubscript{2}/SiO\textsubscript{2} microbeads for hydrophilic interac-
tion liquid chromatography (HILIC) separation of compounds having strong polarity (such as nucleobases, phenolics and alkaloids). However, obvious tailing of chromatographic peaks typically occurs when using chromatographic columns packed with ZrO$_2$/SiO$_2$ based SPs for the separation of phenols, nucleotide bases, and alkaloids. We speculate that this may be due to the strong interactions between the analytes and the exposed Lewis acid sites, which were caused by the large steric hindrance of the modified phosphate groups. Thus, the development of novel end-capping reagents is vital for overcoming the aforementioned limitations.

Fosfomycin (F) contains a phosphonate group and a glycidyl group (Fig. 1). Hydroxyl groups can be formed in either acidic or basic solutions, owing to the hydrolysis reaction of the glycidyl groups. F has been often selected as a modification reagent in the preparation of MgO-ZrO$_2$ based SPs [17]. However, to date, it has not been used as an end-capping reagent. Therefore, in this study, we use F as an end-capping reagent to prepare novel SPs for the separation of polar compounds in HILIC mode. D-glucose-6-phosphate disodium salt (G) and D-fructose 1,6-bisphosphate trisodium salt (FDP) modified ZrO$_2$/SiO$_2$ materials (G-ZrO$_2$/SiO$_2$ and FDP-ZrO$_2$/SiO$_2$) were synthesized and then end-capped with F to improve the chromatographic properties of the SPs for the separation of benzoic acids and alkaloids, respectively. The retention mechanism of the end-capped SPs was evaluated and explained.

For comparison, a common small silane agent (trimethylchlorosilane, T) was used to modify FDP-ZrO$_2$/SiO$_2$ SP, and the resulting T-FDP-ZrO$_2$/SiO$_2$ column was employed to separate alkaloids. The results indicated that the obtained novel F end-capped SPs showed satisfactory results for the separation of polar compounds.

2. Experimental

2.1. Chemicals and reagents

Iressa (98% purity), F, G and FDP were supplied by Shanghai Yuanye Bio-Technology Co., Ltd (Shanghai, China). End-capping
reagent T was supplied by Energy Chemical Co., Ltd. (Shanghai, China). Tetrandrine, lycorine, and tetrahydropalmatine were supplied by Dalian Meilun Biotechnology Co., Ltd. (Dalian, China). Zirconium nitrate pentahydrate, ammonium acetate (NH₄Ac), and sodium hydroxide were supplied by Sinopharm Chemical Reagent Co., Ltd. (Shanghai, China). Analytical grade ethanol was purchased from DaMao Chemical Reagent Factory (Tianjin, China). Berberine chloride (98% purity) was purchased from J&K Scientific Ltd. (Beijing, China). Chromatographic grade methanol (CH₃OH) and acetonitrile (ACN) were obtained from Tedia Inc. (Fairfield, USA). Analytical grade hydrochloric acid, nicotinic acid, acetic acid, ammonia solution, p-hydroxybenzoic acid, benzoic acid, and benzene were purchased from Kernel (Tianjin, China). Bare silica microspheres, having a particle size of 5 μm, surface area of 300 m² g⁻¹, and pore size of 100 Å, were obtained from Fuji Silysia Chemical Ltd. (Kasugai, Japan). Silica based SPs (5 μm, 100 Å) modified with amino and diol groups were supplied by Fuji Silysia Chemical Ltd. (Kasugai, Japan). Deionized purified water, used throughout the study for aqueous solution preparation, was obtained from Hangzhou Wahaha Group Co., Ltd. (Hangzhou, China).

2.2. Instruments and conditions

The packed capillary column (300 × 0.53 mm i.d.) evaluation was conducted using an HPLC instrument equipped with quaternary pumps (Agilent 1260, USA), a manual injection valve with an internal loop of 100 μL (Valco, USA), and a UV detector (an on-column type) from JASCO corporation (Tokyo, Japan). A splitter (tee-piece) was employed to maintain a constant column flow velocity. Finally, the results were obtained and analyzed by using an N2000 chromatographic workstation (Zhejiang University, China).

The packed stainless-steel column (150 mm × 2.1 mm i.d.) was evaluated by using an Agilent 1260 equipped with a diode array detector.

Scanning electron microscopy (SEM, HITACHI S-4800, Japan), along with energy dispersion spectrum (EDS), was utilized to examine the morphology and wt% of Zr on the surface of the materials. Inductively coupled plasma-atomic emission spectrometry (ICP-AES, PerkinElmer, USA) was used to measure the Zr content in the ZrO₂/SiO₂ microbeads. A high-resolution transmission electron microscope (Tecnai G2 F20 S-TWIN, FEI Company, USA) was used to further determine the morphology of the materials. The Fourier transform infrared (FT-IR) spectra of the materials were collected by using FT-IR spectrometer (ThermoFisher Scientific, USA). Thermogravimetric analyzes (TGA) were performed by using an instrument (Mettler 5MP-400W, METTLER-TOLEDO, Switzerland) in the temperature range of 30–900 °C at a heating rate of 10 °C/min. Nitrogen adsorption-desorption measurements were performed on a Quadrasorb S14 (Florida, USA) apparatus, before measurement, and the materials were dried at 60 °C in vacuum for 6 h. The carbon content of the SPs was determined by using a Vario EL III elemental analysis instrument (Elementar, Hanau, Germany).

2.3. Preparation and packing of SPs

2.3.1. Preparation of ZrO₂/SiO₂ material

Similar to our previous work [22], ZrO₂/SiO₂ mesoporous microspheres were prepared as follows. Silica microspheres (5 g) were immersed in an aqueous solution of 0.1 M NaOH and stirred for half an hour. Then, they were washed with deionized water more than six times, and vacuum-dried under 55 °C. Subsequently, 1 g of the activated bare silica was rapidly added into a 0.01 M HCl solution containing 0.5 M zirconium nitrate pentahydrate at 70 °C and stirred for approximately 2 h. The prepared ZrO₂/SiO₂ material was obtained by centrifugation, and then washed separately with both deionized water and ethanol approximately three times each. The obtained material was dried at 60 °C for approximately 8 h and calcined at 550 °C for approximately 6 h in an air atmosphere in a furnace.

2.3.2. Preparation of G modified ZrO₂/SiO₂ (G-ZrO₂/SiO₂) materials

The G-ZrO₂/SiO₂ material was prepared by adding 0.4 g of the ZrO₂/SiO₂ material into 20 mL of an aqueous solution containing 20 mM of G, followed by vigorous stirring at 60 °C for 15 h. The resulting particles were collected and separately washed thrice with deionized water and ethanol. The resulting G-ZrO₂/SiO₂ material was dried in a vacuum oven at 55 °C for approximately 8 h and stored in capped bottles until modification in the next step. The FDP-ZrO₂/SiO₂ materials were synthesized using a similar approach.
three times separately with deionized water and ethanol. Finally, the obtained F-G-ZrO$_2$/SiO$_2$ material was dried at 55 °C for 8 h and stored in centrifugal tubes. F-FDP-ZrO$_2$/SiO$_2$ microspheres were synthesized by applying a similar process with minor modifications using FDP-ZrO$_2$/SiO$_2$ porous microspheres instead of F-G-ZrO$_2$/SiO$_2$ porous microspheres.

2.3.3. End-capping of FDP-ZrO$_2$/SiO$_2$ material with T
FDP-ZrO$_2$/SiO$_2$ (1 g) was dissolved in 50 mL of anhydrous toluene, followed by the addition of end-capping reagent T. The dispersion was stirred at a suitable rate for 24 h under N$_2$ protection. The resulting T-FDP-ZrO$_2$/SiO$_2$ SP was collected via centrifugation and washed successively with anhydrous toluene and ethanol. Finally, the T-G-ZrO$_2$/SiO$_2$ material was dried at 55 °C overnight and stored in centrifugal tubes.

2.4. Investigation of column properties

2.4.1. Column preparation
The materials were packed into capillary columns by using a dry packing method, as previously mentioned [23]. In the procedure, fused-silica capillary tubing (300 mm × 0.53 mm i.d.) supplied by Reafine Chromatography Ltd. (Hebei, China) was used. In the evaluation procedure, a split ratio of 1:100 was chosen. The detection window was prepared by removing the polyimide coating connected to an empty capillary (100 μm i.d.). Acidic and alkaline analytes were utilized to evaluate the performance of the column. The stainless-steel column (150 mm × 2.1 mm i.d.) was packed by employing a slurry method under a pressure of 50 MPa. The column was then flushed with ACN (1.0 mL/min) by using an Agilent 1260 for more than 20 column volumes before evaluation.

2.4.2. Standard solutions preparation and column evaluation
The acidic analytes were a mixture of benzoic acid (1000 mg L$^{-1}$), p-hydroxybenzene acid (1000 mg L$^{-1}$) and nicotinic acid (1000 mg L$^{-1}$). These were eluted using a mobile phase of ACN-20 mM NH$_4$Ac/acetic acid at pH = 4.0 (88:12, v/v) as the solvent and were detected at 230 nm. The basic analyte mixture was as follows: 900 mg L$^{-1}$ of berberine, 800 mg L$^{-1}$ of 1300 mg L$^{-1}$ of tetrahydropalmatine, and 2100 mg L$^{-1}$ of tetrandrine. These were eluted using a mobile phase of ACN-20 mM NH$_4$Ac/ammonia at pH = 9.0 (85:15, v/v) and were detected at 280 nm. The retention factor ($k$) can be obtained based on the following equation: $k = (t_r - t_0)/t_0$, where $t_r$ is the retention time of the analyte and $t_0$ is the retention time of the unretained compound. The $k$ values represent retention of analyte. The evaluation procedure was performed at about 25 °C.

2.4.3. Acid-base stability investigation
In this study, the acid-base stability of the F-FDP-ZrO$_2$/SiO$_2$ column was evaluated under the highest and lowest pH conditions for five days. The base stability of the F-FDP-ZrO$_2$/SiO$_2$ column was studied by using berberine and naphthalene as analytes, and the separation was performed under the following conditions: 85:15 (v/v) ACN-20 mM NH$_4$Ac-NaOH (pH = 12). The acid stability of the F-FDP-ZrO$_2$/SiO$_2$ column was investigated by using benzoic acid and naphthalene as the target analytes, and a mobile phase of 85:15 (v/v) ACN-20 mM NH$_4$Ac-CH$_3$COOH (pH = 3.0) was utilized in the process. The relative retention factors were also examined.

2.4.4. Analysis of benzoic acid in Sprite
At present, benzoic acid is universally used as an antiseptic and is added to many prepared foods and drinks. Thus, the analysis of this antiseptic is important. Standard solutions of benzoic acid

were prepared (10, 50, 100, 500, and 1000 mg L−1), and a calibration curve was drawn. Sprite (20 mL) was added into a 25 mL plastic centrifuge tube and degassed with an ultrasonic cleaner for approximately 15 min. Next, ammonium hydroxide (25%) was added into the solution to neutralize the pH. After that, water was added into the centrifuge tube to 25 mL, and the solution was filtered through a filter membrane with a pore size of 0.22 µm.

3. Results and discussion

3.1. Synthesis of F end-capped ZrO2/SiO2 materials

The synthesis of ZrO2/SiO2 based SPs is schematically shown in Fig. 1A. Firstly, ZrO2/SiO2 was prepared by adding bare silica porous microspheres to an aqueous solution containing Zr4+. The subsequent hydrolysis reaction of Zr4+ and the calcination procedure resulted in the formation of a ZrO2 shell on the silica microbeads. Lewis base reagents G or FDP were adsorbed onto the Lewis acid sites on the inner and outer surfaces of the ZrO2/SiO2 microbeads. Finally, the residual Lewis acid sites of the synthesized materials (FDP-ZrO2/SiO2 or G-ZrO2/SiO2) were end-capped with the small molecule, F, as shown in Fig. 1A.

3.2. Characterization of the materials

The results of the ICP-AES measurement indicated that the wt.% of Zr on the surface of the ZrO2/SiO2 particles was 5.05%, and no Zr was detected on bare silica, confirming that the ZrO2/SiO2 materials were successfully synthesized. As shown in the SEM images (Fig. 2), the prepared particles (ZrO2/SiO2, G-ZrO2/SiO2, F-G-ZrO2/SiO2, T-FDP-ZrO2/SiO2, FDP-ZrO2/SiO2, and F-DPD-ZrO2/SiO2) have particle sizes of approximately 5 μm and are spherical with no agglomerated appearance, which are very similar to the appearance of the bare silica particles. This illustrates that the precipitation of the ZrO2 layer on the surface of the silica sphere did not cause any aggregation, conglomeration, or cracks. The well-preserved morphology of metal oxide coated silica is of great significance for the final chromatographic separation. The EDS data further verified the successful coating of the ZrO2 layer on the surface of the silica microbeads (Table 1). As observed in the TEM images (Fig. S1), homogeneous and rough layers of materials are modified on the surface of the silica particles.

In the FT-IR spectra (Fig. S2), the peaks at 464,800, and 1085 cm−1 correspond to the bending of the Si-O-Si group. In the ZrO2/SiO2 based materials, the stretching of Si-OH near 973 cm−1 disappeared owing to the successful coating of the ZrO2 layer. In the F-FDP-ZrO2/SiO2 and F-G-ZrO2/SiO2 materials, the C-H stretching vibration absorption near 2985 cm−1 demonstrated the successful modification of the organic groups. As shown in Fig. S3, the weight of the materials decreased when heated from 30 °C to 260 °C, indicating the evaporation of surface water and removal of unstable compounds. The weight loss of the materials modified by the organic groups was greater than that of the bare silica and ZrO2/SiO2 particles. These results further confirmed the successful modification of the organic groups. The TGA curves of the materials were nearly a plateau in the range of 260–460 °C. After 460 °C, a minor weight loss of the materials occurred (approximately 1%).

Multipoint nitrogen adsorption-desorption experiments were used to measure the pore structure of the materials. The pore size distribution of the materials is shown in Fig. 3, and the pore structure data are listed in Table 2. Most materials display a narrow pore size distribution (approximately 9 nm). The N2 adsorption-desorption isotherms depicted in Fig. S4 indicate that the materials exhibit type IV isotherms, suggesting that the pore structure of the materials is almost cylindrical, the results show that the mesopores of the prepared materials are still well-preserved after modification.

Fig. 6. Effects of ACN concentration (a), pH for aqueous solution (b), and NH4Ac concentration (c) on the k of the benzoic acids on the F-FDP-ZrO2/SiO2 column. Chromatographic conditions: (a) ACN-20 mM NH4Ac (pH = 4.0), (b) 88% ACN-12% 20 mM NH4Ac, and (c) 88% ACN-12% NH4Ac/ammonia (pH = 4.0).

The excellent physical properties of the prepared particles are very important for HPLC separation. To further demonstrate the stability and the alkali resistance of the prepared ZrO$_2$/SiO$_2$ particles, the materials were immersed in a solution containing NaOH (0.5 M) for 3 h. The morphology of the ZrO$_2$/SiO$_2$ material changed slightly, while the bare silica was nearly completely dissolved (Fig. S5). These results confirmed that the silica material was successfully covered with a ZrO$_2$ shell, which improved the basic stability of the material. The carbon content of the F-G-ZrO$_2$/SiO$_2$, G-ZrO$_2$/SiO$_2$, F-FDP-ZrO$_2$/SiO$_2$, FDP-ZrO$_2$/SiO$_2$, ZrO$_2$/SiO$_2$, and bare silica materials was determined by elemental analysis. Table S1 indicates that G and FDP are successfully modified onto the ZrO$_2$/SiO$_2$ particles. Furthermore, the G-ZrO$_2$/SiO$_2$ and FDP-ZrO$_2$/SiO$_2$ materials are successfully end-capped by F.

### 3.3. Evaluation of F end-capped SPs

The ideal SP should give high selectivity, good symmetrical peak shape, good chemical stability and incompressibility, low mass transfer resistance and reusability. Alkaloids and benzoic acids (Fig. S6) were chosen as standard polar compounds to evaluate the prepared SPs. The chromatographic properties of the prepared SPs were compared with those of commercial SPs (amino-modified silica and diol-modified silica microbeads).

#### 3.3.1. Chromatographic separation of alkaloids

Alkaloids, including tetrahydropalmatine, iresa, lycorine, berberine and tetrandrine, belong to an important family of pharmacologically active compounds that contain an amine nitrogen atom and are usually isolated from herbal medicines [25,26]. However, they are very difficult to retain in reversed-phase liquid chromatography (RPLC) mode [20], leading to the development of ZrO$_2$ based materials to solve the retention problem [18,27,28]. Based on these discoveries, we applied the resulting end-capped ZrO$_2$/SiO$_2$ SPs to separate a mixture of alkaloids.

As shown in Fig. 4, the performance of the chromatographic column packed with F-FDP-ZrO$_2$/SiO$_2$ SPs for the alkaloids exhibits a characteristic HILIC retention mode: the retention time of the polar analytes increases when the content of ACN increases from 75 to 95%. The increase in the NH$_4$Ac content (from 0 mM to 40 mM) and pH (from 7 to 11) of the mobile phase resulted in a decrease in k'. This was mainly due to the interactions of electrostatic repulsion, ion exchange and hydrogen bonding between the SPs and the analytes. The chromatographic properties of the commercial diol-modified silica SPs column were evaluated using alkaloids under different mobile phases (Fig. S7). The optimal mobile phase was determined to be ACN-20 mM NH$_4$Ac/ammonia solution at pH = 9.0 (85:15, v/v).

Fig. 5 and Table 3 present the chromatographic separation performances of columns packed with the prepared F-FDP-ZrO$_2$/SiO$_2$, F-G-ZrO$_2$/SiO$_2$, FDP-ZrO$_2$/SiO$_2$, G-ZrO$_2$/SiO$_2$, ZrO$_2$/SiO$_2$, and com-

mercials (bare silica, amino-modified silica, and diol-modified silica SPs). A baseline separation of alkaloids was achieved with the F-FDP-ZrO2/SiO2 column, yielding the overall best column efficiency of 31,700 plates/m for berberine. The chromatographic performance of the F-G-ZrO2/SiO2 SP was better than that of the G-ZrO2/SiO2 SP. The results indicate that the end-capping process is of great significance for improving chromatographic performance. To further investigate the advantages of the end-capping reagent F, trimethylchlorosilane (a common small silane) was used as an end-capping reagent on the surface of FDP-ZrO2/SiO2. The resulting SP (T-FDP-ZrO2/SiO2) was slurry-packed into a stainless-steel column (150 mm × 2.1 mm i.d.). The T-FDP-ZrO2/SiO2 column was used for the separation of alkaloids; however, berberine and tetrandrine could not be separated, as shown in Fig. S8. F showed superior end-capping properties over T. Finally, the separation reproducibility of the F-FDP-ZrO2/SiO2 SP for alkaloids was evaluated. The relative standard deviation (RSD) values for batch-to-batch and run-to-run were less than 4.9% and 0.9%, respectively, suggesting that F-FDP-ZrO2/SiO2 has good reproducibility (Fig. S9).

3.3.2. Separation of benzoic acids

Benzoic acids have garnered considerable interest in the fields of food and drug production [29]; however, it has been reported that benzoic acids cannot be separated on a bare ZrO2 column. A possible reason for this is that the benzoic acids could be strongly adsorbed by the Lewis acid sites on the ZrO2 materials [30]. A mixture of benzene, benzoic acid, nicotinic acid, and p-hydroxy benzoic acid was utilized to explore the retention mechanism of the columns packed with synthesized SPs and commercial SPs (including bare silica and diol-modified silica). As shown in Fig. 6, on the F-FDP-ZrO2/SiO2 column, the elution orders of benzoic acids were benzene < benzoic acid < p-hydroxy benzoic acid < nicotinic acid, which are consistent with their log P values (the partition coefficients of the compounds between octanol and water, as shown in Fig. S6). The k’ value of most analytes increases with an increase in the ACN content in the mobile phase. The NH4Ac content in the mobile phase and the pH influence on the k’ value of the benzoic acids. These results imply that the separation of benzoic acids occurs via mixed-mode retention mechanisms, including hydrophilic interactions, ion exchange, and hydrogen bond interactions.

As shown in Fig. 7 and Table 4, the chromatographic properties of the prepared F-FDP-ZrO2/SiO2 column are better than those of the commercial columns. These results suggest that F can be used as an end-capping reagent. The batch-to-batch and run-to-run reproducibility of the F-FDP-ZrO2/SiO2 column for the separation of benzoic acids was also evaluated. Three batches of F-FDP-ZrO2/SiO2 materials were synthesized under the same reaction conditions, and dry-packed into columns. As shown in Fig. S10, the batch-to-batch and run-to-run RSD values are less than 6.2% and 1%, respectively. The results indicated that the end-capped SPs have good re-

peatability. In addition, the resulting F-FDP-ZrO2/SiO2 SP showed application potential for the chromatographic separation of ginsenosides (as seen in Fig. S11).

3.3.3. Acid-base stability investigation
The acid-base stability of the F-FDP-ZrO2/SiO2 column was evaluated at a pH of 3.0 and 12. As shown in Fig. 8(a), the k of berberine decreases approximately 60% after 1900 column volumes elution in a basic mobile phase. As shown in Fig. 8(b), the k of benzoic acid decreases by approximately 30% after 5 days of elution under acidic conditions. The results demonstrated that the SPs endcapped with F showed proper acid-base stability.

3.3.4. Analysis of benzoic acid in Sprite
As shown in Fig. S12, a plot of the peak area (y) against concentration (x, mg L⁻¹) of benzoic acid standards yields a straight line from 10 to 1000 mg L⁻¹, with a resulting equation of y = 1034.5600 x - 4680.9063 ( n = 3, R² = 0.9997). The recovery of benzoic acid in Sprite ranged from 98.10 to 102.12%. A content of 263.01 mg L⁻¹ benzoic acid was detected in the commercial samples of Sprite (n = 3). The results showed that the F-FDP-ZrO2/SiO2 column could be used for the analysis of practical samples.

4. Conclusion
A new end-capping reagent (F) was employed to prepare ZrO2/SiO2 based HILIC SPs. The resulting SPs exhibited better chromatographic performance than the SPs without end-capping. The baseline separation and good peak shape of alkalioids and benzoic acids demonstrated that the end-capping reagent is very valuable for improving the chromatographic performance of SPs. Additionally, the synthesized F-FDP-ZrO2/SiO2 materials facilitate the analysis of benzoic acid in Sprite and the separation of ginsenosides. Moreover, this modification strategy can be widely applied to the synthesis of metal oxid (e.g., TiO2 or ZrO2) based materials having abundant Lewis acid sites. The synthesized SPs have significant potential for solving the problems of the separation and purification of polar pharmaceuticals.
